ABSTRACT

As a result of great surface area and a great number of energetic sites, ceramic nanocomposites are being considered as good adsorbents and catalysts. Al_2O_3 nanoparticles are widely used in high-tech applications owing to their excellent properties. Besides, Bi-based oxides have been the center of attention for applications such as remediation of hazardous wastes and wastewater photochemical degradation of organic contaminants and remediation of hazardous wastes. In this research, the synthesis of $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ nanocomposite and its mechanical properties as a novel composition were investigated. The results showed that the prepared $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ sample exhibited the $\text{Al}_4\text{Bi}_2\text{O}_9$ crystalline peaks. Additionally, the prepared nanocomposite showed no impurities. The mechanical properties of the $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ sample were improved in comparison with Al_2O_3 , Bi_2O_3 , and $\text{Bi}_2\text{O}_3\text{-Al}_2\text{O}_3$, which offer it as a promising alternative to $\text{Bi}_2\text{O}_3\text{-Al}_2\text{O}_3$ composite ceramic.

Novel composition

1. Introduction

Due to significant advances in the production of nanostructured materials with new properties, many researchers have focused on the engineering of multi-functional macroscopic materials by structure design at the nanometer scale. One of the fast-growing areas of composites research is the development of nanocomposites [1, 2].

Novel material properties can be achieved by decreasing the particle size to the nanometer scale [3]. In addition to the properties of the matrix and reinforcement, the properties of nanocomposite depend on the morphology and interfacial characteristics of the constituents [4, 5]. The surface area to volume ratio of reinforcements is a morphological property determining the relationship between the structure and property of nanocomposites [3].

Nanocrystalline ceramics have the potential to be used as catalyst supports [6, 7] and adsorbents [8-11] owing to possessing a large surface area and a high number of energetic sites for the interaction with contaminants [12, 13]. Due to the excellent properties of Al_2O_3 nanoparticles, they have found ways to the ceramic industry and high-tech applications [14]. Crystal phases of Al_2O_3 include η , δ , θ , γ , and $\alpha\text{-Al}_2\text{O}_3$, and among all these phases, the strongest absorption belongs to α and γ due to possessing the highest surface area for the majority of photocatalytic reactions [15-18].

Owing to properties such as good environmental compatibility, dielectric permittivity, low toxicity, high retractile indicator, and convenient band gap energy about 2.8 eV, Bi-based oxides, especially Bi_2O_3 , have been widely studied. These oxides are good candidates for different green applications including remediation of hazardous waste substances and photochemical (visible light) degradation of organic contaminants

in wastewater [18-25]. Bi_2O_3 is used in some industries including optical coatings, gas sensors, optoelectronics, and solid oxide fuel cells [26, 27]. Trivedi et al. [28] studied the thermal, physical, and atomic properties of Bi_2O_3 treated by biofield energy [29]. According to the results, the physical and atomic characteristics of Bi_2O_3 changed by biofield energy treatment, which makes it more useful to be used in solid oxide fuel cells [30].

Dehkordi et al. [31] used Transient Liquid Phase (TLP) route by Bi_2O_3 reinforcement to join alumina to alumina. Bi_2O_3 was used because of its low melting point [32]. A thin interlayer of Bi_2O_3 was placed between the ceramic bodies [33]. The results showed the interfacial compound growth between Bi_2O_3 and Al_2O_3 at 880 °C upon the TLP process [34]. Higher mechanical properties of the interfaces were observed for longer joining times. Neiman et al. [35] studied differences between the interaction of micro-sized Al_2O_3 or nano-sized Al_2O_3 with micro-sized Bi_2O_3 [36]. Nano- Al_2O_3 showed higher reactivity and stronger adhesion to micro- Bi_2O_3 leading to the encapsulation of micro- Bi_2O_3 in a shell composed of Al_2O_3 and interaction products [37]. Above 400 °C, the presence of BiAlO_3 , $\text{Al}_2\text{Bi}_{24}\text{O}_{39}$, and $\text{Al}_4\text{Bi}_2\text{O}_9$ phases was confirmed, and at higher temperatures, the main complex intermediate was $\text{Al}_4\text{Bi}_2\text{O}_9$. At 730 °C, phase transfer from $\alpha\text{-Bi}_2\text{O}_3$ to $\delta\text{-Bi}_2\text{O}_3$ was achieved. By further increase in the temperature to 780 °C, the solid phase was decomposed in interaction products, and the $\delta\text{-Bi}_2\text{O}_3$ phase was separated. The grains of $\delta\text{-Bi}_2\text{O}_3$ [38] with high conductivity formed a connected charge percolation resulting in a 2.5-fold conductivity increase between 770 °C to 800 °C.

Different methods are employed for the production of metal oxide nanoparticles including electrodeposition, precipitation, sol-gel, hydrothermal, and combustion methods [39, 40]. A common synthesis method is the sol-gel route. Homogeneity and the production of high purity

materials are some advantages of the sol-gel method [41, 42]. In this study, $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ nanocomposite was synthesized using the sol-gel method and its mechanical properties were evaluated. Based on previous studies regarding the phases formed in Bi_2O_3 and Al_2O_3 nanocomposites, this new nanocomposite is expected to have improved mechanical properties and can be utilized as novel and efficient materials for various applications.

2. Materials and methods

2.1. Materials

All reagents and chemicals i.e. Bismuth (III) nitrate ($\text{Bi}(\text{NO}_3)_3$), Aluminum nitrate nonahydrate ($\text{Al}(\text{NO}_3)_3$) and Ethanolamine (2-Aminoethanol) $\text{C}_2\text{H}_7\text{NO}$ in this research were obtained from Merck (Darmstadt, Germany) without further purification. All Glass containers underwent alkali washing and rinsing before application.

Synthesis procedure

To prepare the samples, 300 mmol of 2-aminoethanol was added to 50 ml of water. Then, the solution was added dropwise to a solution containing aluminum nitrate (40 mmol) and $\text{Bi}(\text{NO}_3)_3$ (40 mmol) in distilled water (200 ml) while the solution was stirred during mixing. Stirring continued for another 60 min. Finally, the precipitates were filtered, washed, and heat-treated at 600°C for 3 h.

2.2. Characterization

The tensile properties of the nanocomposites were evaluated as per D3039-ASTM at room temperature at a crosshead speed of 5 mm/min using an Instron 6025 device. The samples were prepared by sintering (600°C for 3 h) with dimensions of $150 \times 25 \times 3$ mm. A three-point bending tester (Instron 6025) was used to measure the bending strength of the nanocomposites. The test was performed according to D790-ASTM at a crosshead speed of 2 mm/min at room temperature. The length, width, and thickness of the samples were 90 mm, 10 mm, and 3 mm, respectively. A Zwick pendulum impact tester was used to study the impact strength of the samples. The results are the average of five repetitions.

The Vickers hardness of the samples was measured at ambient temperature using Instron, Wilson-Wolpert Tukon 2100B. The applied load

Fig. 2. SEM micrographs of the $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ nanopowder.

Fig. 3. Vickers hardness of the Bi_2O_3 , Al_2O_3 , $\text{Bi}_2\text{O}_3\text{-Al}_2\text{O}_3$, and $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ samples.

and loading time was 10 N and 10 s, respectively. The samples were polished prior to the measurement and the measurement was repeated three times for each sample. The structure of the powders was studied using X-ray diffraction analysis (XRD) (Philips X' Pert, The Netherlands) operating at 30 mA and 40 kV. $\text{Cu-K}\alpha$ radiation with $\lambda = 15.405$ nm was used, and the step size was 0.02° . X'Pert HighScore software was utilized to identify the crystalline phases of the powder [43]. The gold-coated fracture surface of the samples was studied by the scanning electron microscopy (SEM) analysis (Hitachi S-3400N, Japan). The operating voltage of the microscope was 15 kV [44, 45].

3. Results and discussion

3.1. Microstructural analysis

To identify the crystal structure and parameters, the quantitative and non-destructive method of XRD is widely used. The XRD diffraction pattern of the prepared powder is illustrated in Fig.1. The peaks appeared at 2θ of 24.79° , 25.85° , 27.13° , 27.66° , 28.09° , 31.45° , 33.20° , and 46.51° are related to the Bi_2O_3 phase and the peaks at 15.83° , 29.64° , 30.21° , 35.21° , 41.10° , 48.82° , 52.01° , 54.91° , and 59.35° represent the presence of $\text{Al}_4\text{Bi}_2\text{O}_9$. The $\text{Al}_4\text{Bi}_2\text{O}_9$ and Bi_2O_3 phases have monoclinic and orthorhombic crystal structures, respectively. Additionally, no impurities were detected in the powder composition. The average crystal sizes of the powder estimated from the Debye-Scherrer equation was obtained to be around 24 nm. The microstructure of the $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ nanopowder is illustrated in Fig. 2. As seen, the particle size of the nanopowder is in the range of 30-60 nm.

3.2. Mechanical properties

The results of Vickers hardness for Al_2O_3 , Bi_2O_3 , $\text{Bi}_2\text{O}_3\text{-Al}_2\text{O}_3$, and $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ are represented in Fig. 3. According to the results, the $\text{Bi}_2\text{O}_3\text{-Al}_4\text{Bi}_2\text{O}_9$ sample showed the highest hardness compared to other

Fig. 4. (a) Flexural strength and (b) flexural modulus of the Bi₂O₃, Al₂O₃, Bi₂O₃-Al₂O₃, and Bi₂O₃-Al₄Bi₂O₉ samples

samples, revealing that the Bi₂O₃-Al₄Bi₂O₉ composite can be considered as a good alternative to the Al₂O₃-Bi₂O₃ composite. The Vickers hardness data indicated that Bi-O chemical bonds in Bi₂O₃-Al₄Bi₂O₉ composite are considerably strong. The Bi₂O₃-Al₄Bi₂O₉ samples exhibited 260.29, 302.21, and 37.64 MPa enhancement in Vickers hardness compared to Al₂O₃, Bi₂O₃, and Bi₂O₃-Al₂O₃, respectively. The increase in hardness in the composite indicates a good bond between the Bi₂O₃ and Al₂O₃.

The bending test was carried out to measure the flexural modulus and flexural strength of the samples. The flexural modulus and flexural strength of Al₂O₃, Bi₂O₃, Bi₂O₃-Al₂O₃, and Bi₂O₃-Al₄Bi₂O₉ samples are observed in Fig. 4. The results show that the highest value of bending strength is associated with Bi₂O₃-Al₄Bi₂O₉. Significant increase in flexural modulus and flexural strength of Bi₂O₃-Al₄Bi₂O₉ sample exhibited in Fig. 4. When we use Bi₂O₃ its impact on its mechanical properties such as flexural modulus and flexural strength can be seen. The good effect of Bi₂O₃-Al₄Bi₂O₉ can be attributed to the proper relationship created between Al₂O₃ and Bi₂O₃.

Failure toughness of the samples is obtained from the impact test. As shown in Fig. 5, The fracture toughness of the Al₂O₃, Bi₂O₃, Bi₂O₃-Al₂O₃, and Bi₂O₃-Al₄Bi₂O₉ samples are 0.5, 0.6, 0.8, and 1.8, respectively. The Bi₂O₃-Al₄Bi₂O₉ samples showed the highest fracture toughness compared to other samples and Bi₂O₃ show the lowest fracture toughness. The most important reason that can be the cause of this result is the formation of agglomerates and agglomerates at Bi₂O₃, where failure occurs earlier than expected.

4. Conclusions

In this research, Bi₂O₃-Al₄Bi₂O₉ nanocomposite was synthesized via the sol-gel method. The formation of the Al₄Bi₂O₉ was confirmed by the XRD analysis without any impurities in the composite structure. The

Fig. 4. Fracture toughness of the Bi₂O₃, Al₂O₃, Bi₂O₃-Al₂O₃, and Bi₂O₃-Al₄Bi₂O₉ samples

mechanical properties of the Al₂O₃, Bi₂O₃, Bi₂O₃-Al₂O₃, and Bi₂O₃-Al₄Bi₂O₉ samples were evaluated and the results showed that Vickers hardness, bending strength, and failure toughness of Bi₂O₃-Al₄Bi₂O₉ was the highest amount among other samples. Therefore, this ceramic composite can be a good alternative to the Bi₂O₃-Al₂O₃ composite.
